

# Metal Industry Indicators

## Indicators of Domestic Primary Metals, Steel, Aluminum, and Copper Activity

---

August 2006

---

The primary metals leading index increased in July, and its 6-month smoothed growth rate resumed its upward trend after a dip in June. Activity in the U.S. metals industry is likely to grow at a modest-to-moderate pace in the near future. The metals price leading index growth rate fell sharply in June, which normally would indicate a drop in metal prices. However, concern over supply disruptions has created volatility in some metals price growth.

The primary aluminum and the aluminum mill products indexes are suspended because of discontinued availability of industry-specific historical data. The USGS will continue to calculate the steel and copper composite indexes.

The **primary metals leading index** increased to 153.5 in July from a revised 152.2 in June, and its 6-month smoothed growth rate lifted to 7.7% from a revised 7.4% in June. The 6-month smoothed growth rate is a compound annual rate that measures the near-term trend. Normally, a growth rate above +1.0% signals an upward trend for future growth in metals activity, while a growth rate below -1.0% indicates a downward trend. For an explanation of these indexes and a definition of the primary metals industry, [see page 10](#).

The average workweek in primary metals establishments has increased the last 3 months; it contributed 0.7 percentage points to the net increase in the leading index in July. The JOC-ECRI metals price index growth rate edged up in July and made a 0.3-percentage-point contribution. The Institute for Supply Management's PMI rebounded, contributing 0.2 percentage points. The PMI has remained above the 50.0 threshold that denotes increased future domestic manufacturing activity for more than 2 years. In contrast, the combined S&P stock price indexes for construction and farm machinery companies and for industrial machinery companies posted its second consecutive decrease in July, holding the leading index back 0.3 percentage points. Only four of the leading index's eight components were available for the July index calculation. The primary metals leading index will likely be revised next month when the remaining four components become available.

While the primary metals leading index growth rate increased in July, it is accelerating at a slower pace than earlier this year. The

leading index growth rate, along with slower U.S. and global economic activity, is suggesting a modest-to-moderate increase in domestic primary metals industry activity growth.

The **steel leading index** decreased 0.6% to 119.9 in June, the latest month for which it is available, from a revised 120.6 in May. Its 6-month smoothed growth rate decreased to 2.5% from a revised 4.6%. The first decrease in the S&P stock price index for steel companies in 8 months made the largest negative impact on the steel leading index. Permits issued for new housing units continued to fall and also had a significant pull on the leading index. The inflation-adjusted M2 money supply growth rate rose and offset some of the declines in other indicators in June. The steel leading index growth rate has lowered since the beginning of the year and is now suggest modest-to-moderate activity growth in the U.S. steel industry in the months directly ahead.

The **copper leading index** fell 2.1% to 129.2 in June from 132.0 in May, and its growth rate dropped to 0.8% from 5.4% in May. All of the index's indicators decreased in June, but some of the declines were setbacks from unusually high levels in May. A reduction in overtime hours in copper rolling, drawing, extruding, and alloying plants made the largest negative contribution to the copper leading index's decrease. The lower S&P stock price index for building products companies, the LME copper price, and housing permits issued also had negative impacts on the leading index. Still, the concern over copper supplies will likely keep the domestic copper industry activity moving along at a slow-to-modest growth pace in the near term.

## Supply Disruptions Promote Metals Price Volatility

The **metals price leading index** decreased 0.7% in June, the latest month for which it is available, to 106.4 from a revised 107.2 in May. Its 6-month smoothed growth rate dropped close to negative territory to 0.1% from a revised 0.9% in May. All three of its available indicators made negative contributions to the leading index. The growth rate of the index measuring the trade-weighted average exchange value of other major currencies against the U.S. dollar made the largest negative contribution, -0.3 percentage points, to the net decrease in the metals price leading index. The yield spread between the U.S. 10-year Treasury Note and the federal funds rate continued to tighten and made a -0.1-percentage-point contribution. The decline in the growth rate of the inflation-adjusted value of new orders for U.S. nonferrous metal products rounded to zero. The fourth index component, the growth rate of the Economic Cycle Research Institute's (ECRI) 18-Country Long Leading Index, was only available through May. It declined to its lowest level of the year

to suggest slow-to-modest growth for most global economies. The ECRI 18-Country Long Leading Index signals changes in the growth of economic activity in major industrialized countries about 5 months in advance.

The growth rate of the inflation-adjusted value of inventories of U.S. nonferrous metal products, which is an indicator of metals supply, increased in June. This indicator usually moves inversely with the price of metals. The U.S. and many global economies have lowered their metals demand from the robust levels of earlier this year. This normally would pull metals prices lower, as the leading index of metals prices indicates. However, strikes and subsequent supply disruptions may keep prices climbing.

The business cycle and inventories are only two factors in metals price determination. Other factors that affect prices include changes in metals production, speculation, strategic stockpiling, foreign exchange rates, geopolitical instability, and production costs.

**Table 1.**  
**Leading Index of Metal Prices and Growth Rates of the Nonferrous Metals Price Index, Inventories of Nonferrous Metal Products, and Selected Metal Prices**

	Leading Index of Metal Prices (1967=100)	Six-Month Smoothed Growth Rates				
		MII Nonferrous Metals Price Index	U.S. Nonferrous Metal Products Inventories (1982\$)	Primary Aluminum	Primary Copper	Steel Scrap

NA: Not available    r: Revised

**Note:** The components of the Leading Index of Metal Prices are the spread between the U.S. 10-year Treasury Note and the federal funds rate, and the 6-month smoothed growth rates of the deflated value of new orders for nonferrous metal products, the Economic Cycle Research Institute's 18-Country Long Leading Index, and the reciprocal of the trade-weighted average exchange value of the U.S. dollar against other major currencies. The Metal Industry Indicators (MII) Nonferrous Metals Price Index measures changes in end-of-the-month prices for primary aluminum, copper, lead, and zinc traded on the London Metal Exchange (LME). The steel scrap price used is the price of No. 1 heavy melting. Inventories consist of the deflated value of finished goods, work in progress, and raw materials for U.S.-produced nonferrous metal products (NAICS 3313, 3314, & 335929). Six-month smoothed growth rates are based on the ratio of the current month's index or price to its average over the preceding 12 months, expressed at a compound annual rate.

**COPPER: LEADING AND COINCIDENT GROWTH RATES, 1984-2006**

## Explanation

Each month, the U.S. Geological Survey tracks the effects of the business cycle on five U.S. metal industries by calculating and publishing composite indexes of leading and coincident indicators. Wesley Mitchell and Arthur Burns originated the cyclical-indicators approach for the economy as a whole at the National Bureau of Economic Research in the mid-1930s. Over subsequent decades this approach was developed and refined, mostly at the National Bureau, under the leadership of Geoffrey H. Moore.<sup>1</sup>

A business cycle can briefly be described as growth in the level of economic activity followed by a decline succeeded by further growth. These alternating periods of growth and decline do not occur at regular intervals. Composite indexes, however, can help determine when highs and lows in the cycle might occur. A composite index combines cyclical indicators of diverse economic activity into one index, giving decision makers and economists a single measure of how changes in the business cycle are affecting economic activity.

The indicators in the metal industry leading indexes historically give signals several months in advance of major changes in a coincident index, a measure of current metal industry activity. Indicators that make up the leading indexes are, for the most part, measures of anticipations or new commitments to various economic activities that can affect the metal industries in the months ahead.

Composite coincident indexes for the metal industries consist of indicators for production, shipments, and total employee hours worked. As such, the coincident indexes can be regarded as measures of the economic health of the metal industries.

The metal industry coincident indexes reflect industry activity classified by the U.S. Standard Industrial Classification (SIC) and the North American Industry Classification System (NAICS). Of the five metal industries, primary metals (NAICS 331) is the broadest, containing 25 different metal processing industries. Steel, aluminum, and copper are specific industries within the primary metals group.

The SIC was the main vehicle used by the U.S. Government and others in reporting industry economic statistics throughout most of the last century. Starting with the 1997 U.S. Economic Census, the U.S. Government began using the NAICS, which classifies economic data for industries in Canada, Mexico, and the United States. In general, metal industry indexes starting in 1997 begin to reflect the NAICS classification, while indexes for earlier years follow the SIC. Hence, composite indexes from 1997 forward are not entirely consistent with those of earlier years.

The largest change to primary metals because of the NAICS deals with other communication and energy wire manufacturing (NAICS 335929). Under NAICS, this manufacturing has been removed from primary metals and added to electrical equipment, appliance, and component manufacturing. Because monthly shipments and new orders for this wire are not available, the USGS is estimating their values from 1997 onward and adding them to the appropriate metal industry indicators and indexes to maintain consistency.

---

<sup>1</sup>**Business Cycle Indicators, A monthly report from The Conference Board** (March 1996).

There are other small changes to the primary metals industry because of the switch to the NAICS. Coke oven activity not done by steel mills, for example, is removed and alumina refining, a part of industrial inorganic chemical manufacturing under the SIC, is added. Since the historic trends of the composite indexes are not affected by these small changes, the USGS is not making specific adjustments to the indexes for them for the periods before and after 1997.

The metal industry leading indexes turn before their respective coincident indexes an average of 8 months for primary metals and 7 months for steel and copper. The average lead time for the primary aluminum leading index is 6 to 8 months, and the average lead time for the aluminum mill products leading index is 6 months.

The leading index of metal prices, also published in the *Metal Industry Indicators*, is designed to signal changes in a composite index of prices for primary aluminum, copper, lead, and zinc traded on the London Metal Exchange. On average, this leading index indicates significant changes in price growth about 8 months in advance.

The growth rate used in the *Metal Industry Indicators* is a 6-month smoothed growth rate at a compound annual rate, calculated from a moving average. Moving averages smooth fluctuations in data over time so that trends can be observed. The 6-month smoothed growth rate is based upon the ratio of the latest monthly value to the preceding 12-month moving average.

$$\left[ \left( \frac{\text{current value}}{\text{preceding 12-month moving average}} \right)^{\frac{12}{6.5}} - 1.0 \right] * 100$$

Because the interval between midpoints of the current month and the preceding 12 months is 6.5 months, the ratio is raised to the 12/6.5 power to derive a compound annual rate.

The growth rates measure the near-term industry trends. They, along with other information about the metal industries and the world economy, are the main tools used to determine the outlook of the industries. A 6-month smoothed growth rate above +1.0% usually means increasing growth; a rate below -1.0% usually means declining growth.

**The next update for these indexes is scheduled for release on the World Wide Web at 10:00 a.m. EDT, Friday, September 15. The address for *Metal Industry Indicators* on the World Wide Web is: <http://minerals.usgs.gov/minerals/pubs/mii/>**

The *Metal Industry Indicators* is produced at the U.S. Geological Survey by the Minerals Information Team. The report is prepared by Gail James (703-648-4915; e-mail: [gjames@usgs.gov](mailto:gjames@usgs.gov)) and Ken Beckman (703-648-4916; e-mail: [kbeckman@usgs.gov](mailto:kbeckman@usgs.gov)). The former Center for International Business Cycle Research, under the direction of Dr. Geoffrey H. Moore, and the former U.S. Bureau of Mines developed the metal industry leading and coincident indexes in the early 1990s. Customers can send mail concerning the *Metal Industry Indicators* to the following address:
